Award Number: W81XWH-13-1-0107

TITLE: Uncovering the Role of BMP Signaling in Melanocyte Development and Melanoma Tumorigenesis

PRINCIPAL INVESTIGATOR: Craig J. Ceol, Ph.D.

CONTRACTING ORGANIZATION: University of Massachusetts Medical School
Worcester, MA 01655

REPORT DATE: June 2015

TYPE OF REPORT: Annual Report

PREPARED FOR: U.S. Army Medical Research and Materiel Command
Fort Detrick, Maryland 21702-5012

DISTRIBUTION STATEMENT: Approved for Public Release;
Distribution Unlimited

The views, opinions and/or findings contained in this report are those of the author(s) and should not be construed as an official Department of the Army position, policy or decision unless so designated by other documentation.

REPORT DOCUMENTATION PAGE				Form Approved OMB No. 0704-0188	
Public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing this collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to Department of Defense, Washington Headquarters Services, Directorate for Information Operations and Reports (0704-0188), 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302. 14. ABSTRACT Melanoma is the most aggressive and lethal form of skin cancer. In 2013 over 75,000 Americans were diagnosed with melanoma, and nearly 10,000 died from this disease. It has been known for over a decade that mutations that overactivate the <i>BRAF</i> and <i>NRAS</i> genes promote melanoma formation. At the same time it has also become clear that these mutations are not sufficient for melanoma formation and other genes are involved. Using genomic studies and cross-species comparisons, we identified the BMP factor <i>GDF6</i> as a gene that may cooperate with mutant <i>BRAF</i> to promote melanoma. The aims of this grant are to determine if <i>GDF6</i> does in fact cooperate with mutant <i>BRAF</i> and uncover the mechanisms by which <i>GDF6</i> acts in melanomas and normal melanocytes. Toward these aims, we have used our zebrafish model to demonstrate cooperativity between <i>GDF6</i> and mutant <i>BRAF</i> in accelerating melanoma onset. Furthermore, we have knocked down <i>GDF6</i> in human melanoma cells, finding that loss of <i>GDF6</i> causes cells to cease proliferating. These and other data suggest that <i>GDF6</i> promotes melanoma progression and its withdrawal is detrimental to melanoma cell growth. We are currently investigating whether blocking <i>GDF6</i> function is a viable therapeutic strategy.

INTRODUCTION:

Melanoma is the most aggressive skin cancer, and every year it kills nearly 10,000 Americans and roughly 60,000 people worldwide. A greater understanding of the genetic basis for melanoma is essential for designing new ways to diagnose and treat this disease. Nearly a decade ago, it was discovered that mutations that inappropriately activate the *BRAF* gene are present in over half of all human melanomas. Activated *BRAF* mutations are necessary for formation of these melanomas, but numerous studies have shown that they are not sufficient. To find other genes that cooperate with *BRAF* in creating melanomas, we have used genomic studies and cross-species comparisons to identify several candidates. One of these candidates, *GDF6*, is a BMP factor that is recurrently amplified and upregulated in human and zebrafish melanomas. The purpose of this study is to functionally analyze the role of *GDF6* in melanoma progression. In addition, this study aims to use gain and loss of function studies to determine how *GDF6* acts in melanomas and normal melanocytes. A major goal of this research is to determine if *GDF6* can be used as a diagnostic or prognostic marker in melanoma and is a potential therapeutic target.

BODY:

As requested in the Technical Reporting Requirements, this section describes research progress in reference to each task outlined in the Statement of Work. Below, I restate each task and briefly describe its components. With each task an update on progress made is included.

Task 1: Perform gain and loss of function studies in zebrafish embryos and mammalian cultured cells to determine if GDF6 antagonizes melanocyte development.

In this task, studies in zebrafish and mammalian cultured cells were proposed to determine the effects of *gdf6b* overexpression and *gdf6b* loss on melanocyte development. Zebrafish expressing *gdf6b* in melanocyte progenitors fail to develop melanocytes, suggesting that *gdf6b* inhibits terminal differentiation of melanocytes. We have created a zebrafish strain with a targeted mutation in *gdf6b*. *gdf6b* mutant animals have excess melanocytes, consistent with a role for *gdf6b* in inhibiting melanocyte development. These animals are being further characterized to determine the stage of melanocyte development during which *gdf6b* acts. We have also performed knockdown and overexpression experiments in human cultured melanoma cells. As described below, alteration of *GDF6* levels has profound effects on cell viability and tumorigenic potential.

Task 2: Use established screening procedures in zebrafish to determine if GDF6 overexpression accelerates melanoma onset or exacerbates other properties of melanomas. In addition, use human melanoma cells to determine if GDF6 knockdown in GDF6-positive cells or overexpression in GDF6-minus cells affects tumorigenicity.

To address this task, a zebrafish screening scheme, termed the 'MiniCoopR' assay^{1,2}, was used to determine if *gdf6b* has an effect on melanoma progression. In this assay, melanocyte-deficient animals are injected with DNA that can both rescue melanocytes and overexpress a gene of interest. Zebrafish with rescued melanocytes are monitored weekly for tumors to determine if the gene of interest affects tumor onset as compared to a control gene. When *gdf6b* was overexpressed using MiniCoopR, melanomas arose more quickly as compared to *EGFP* controls (Fig. 1A). *GDF6* was also expressed in cultured human A375 melanoma cells. *GDF6* overexpressing cells were xenotransplanted into nude mice and tumor progression monitored as compared to control A375 cells. *GDF6* overexpression caused tumors to grow much more quickly than controls (Fig. 1B,C). A375 and other human melanoma cell lines express endogenous *GDF6*, so we determined the effects of *GDF6* knockdown in these cell lines. When *GDF6* was knocked down using multiple, independent shRNAs A375 and other melanoma cells underwent programmed cell death (Fig. 2). When knockdown cells were xenotransplanted prior to death, melanoma progression was markedly decreased (Fig. 3). Taken together, these results indicate that *GDF6* is an oncogene and the cell death resulting from its knockdown makes it an excellent target for anti-melanoma therapy.

Knockdown and overexpression cells are being used to determine how *GDF6* acts. The *GDF6* protein is initially made as a proprotein, which is cleaved in cells to generate mature, secreted *GDF6*³. To determine if mature *GDF6* acts as a pro-survival factor, we added recombinant, mature *GDF6* to media of *GDF6* knockdown cells. Recombinant *GDF6* rescued the effects of *GDF6* knockdown (Fig. 4), indicating that *GDF6* can act as a secreted protein to promote melanoma cell survival. These data suggest that targeting soluble, extracellular *GDF6* is a therapeutic strategy for melanoma and possibly other types of tumors. Currently we are characterizing the transcriptomes of *GDF6* to further address the effects of *GDF6* knockdown and overexpression. Analyses thus far are consistent with a role for *GDF6* in promoting cell survival.

Task 3: Use BMP pathway reporters to determine the dynamics of BMP activity in normal melanocytes and melanoma cells. Examine GDF6 expression and mutation status in human melanomas, benign melanocytic lesions and normal melanocytes to determine if modulation of GDF6 activity is consistent with a role in melanoma formation.

A major goal of this task is to assess the effects of *GDF6* on BMP signaling activity. In zebrafish we initially proposed to use a fluorescent reporter to monitor transcriptional output of BMP activity – however, technical difficulties have made this approach untenable. Instead, we have used antibodies that recognized phosphorylated SMAD1/5/8 to measure BMP signaling activity. In zebrafish, melanomas have high levels of *GDF6* protein as well as robust phospho-SMAD expression (Fig. 5). In cultured melanoma cells we similarly detect *GDF6* and phospho-SMAD1/5/8 expression. When *GDF6* is knocked down, phospho-SMAD1/5/8 levels go down (Fig 6), consistent with the notion that *GDF6* signals through SMAD1/5/8 and the BMP signaling pathway.

Additional experiments were performed to determine if *GDF6* acts via the BMP signaling pathway. Knockdown of *SMAD1* resulted in the same cell death phenotype as *GDF6* knockdown, suggesting that both genes act in the same pathway. To directly assess whether *GDF6* acts via the BMP signaling pathway we performed genetic epistasis analyses (Fig. 7). In these epistasis experiments an activated variant of *SMAD1* was used. This variant, *SMAD1DVD*, contains amino acid substitutions in key catalytic residues, resulting in a constitutively active protein⁴. When *GDF6* knockdown was performed in A375 cells expressing *SMAD1DVD*, cell death was suppressed, indicating that *GDF6* acts upstream of or in parallel to *SMAD1*. When such cells were xenotransplanted into immunocompromised mice, they grew much more quickly than *GDF6* knockdown cells, again indicating that *GDF6* acts upstream of *SMAD1*.

Stainings of zebrafish and human tissue samples were used to further investigate the role of *GDF6* and *SMAD1* in melanoma (Fig. 8). In zebrafish melanomas we discovered robust expression of *GDF6* and phospho-*SMAD1*. Similar, robust expression of *GDF6* and phospho-*SMAD1* was observed in human melanoma sections. To determine if there is a correlation between *GDF6* or phospho-*SMAD1* expression and clinical outcome, we have recently stained a tissue microarray of human melanoma tissue cores, each of which has associated clinical data. We are currently analyzing these stainings to determine if increased *GDF6* or phospho-*SMAD1* expression correlates with a poor clinical outcome.

KEY RESEARCH ACCOMPLISHMENTS:

- Overexpression of GDF6 accelerates melanoma onset in zebrafish.
- Overexpression of GDF6 accelerates melanoma onset of A375 cells in xenotransplanted mice.
- Knockdown of *GDF6* causes programmed cell death.
- Recombinant GDF6 protein rescues effects of *GDF6* knockdown.
- Knockdown of *SMAD1* causes programmed cell death.
- Expression of an activated *SMAD1* variant, *SMAD1DVD*, suppresses the effects of *GDF6* knockdown.
- GDF6 and phospho-SMAD1 are robustly expressed in zebrafish melanomas.
- GDF6 and phospho-SMAD1 are robustly expressed in human melanomas.
- Zebrafish with mutant GDF6 have supernumerary melanocytes.

REPORTABLE OUTCOMES:

Presentations during this reporting period include:

- 7th Zebrafish Disease Models Conference, selected talk (abstract appended)
Title: Mechanistic insights into oncogenic glutamate receptor signaling in melanocytes and melanoma
- 22nd International Pigment Cell Conference, selected talk (abstract appended)
Title: Dual mechanisms combine to mediate regeneration of zebrafish melanocytes following injury
- 52nd Annual Meeting of The American Society of Dermatopathology, selected talk (abstract appended)
Title: The novel oncogene *GDF6* promotes melanoma cell survival
- PanAmerican Society for Pigment Cell Research, selected talk (abstract appended)
Title: Identifying *GDF6* as a novel pro-survival melanoma oncogene
- Tufts University, American Cancer Society seminar
Title: Understanding melanoma initiation using the zebrafish
- University of Massachusetts Medical School Hematology/Oncology seminar
Title: The BMP factor *GDF6* is a novel pro-survival melanoma oncogene
- MassBiologics research seminar
Title: The novel melanoma oncogene *GDF6* as a therapeutic target

Cell lines created during this reporting period include:

- *GDF6*-overexpressing melanoma cell lines
- *GDF6*-knockdown melanoma cell lines
- *SMAD1*-overexpressing melanoma cell lines
- *SMAD1*-knockdown melanoma cell lines
- *SMAD1DVD*-overexpressing cell lines

Zebrafish strains created during this reporting period include:

- Strains with loss-of-function mutations in *GDF6*
- Strains with *GDF6* overexpression in melanocytes

Publications include:

- Painter, C.A. and Ceol, C.J. (2014). Zebrafish as a platform to study tumor progression. *Methods in Molecular Biology*, 1176, 143-55.
- Iyengar, S., Kasheta, M. and Ceol, C.J. (2015). Poised regeneration of zebrafish melanocytes involves direct differentiation and concurrent replenishment of tissue-resident progenitor cells. *Developmental Cell*, 33, 631-43.

Fang Liu, Ph.D.
Arvind Venkatesan

CONCLUSION:

In this reporting period we have obtained data that show *GDF6* is a new oncogene in melanoma. These data include gain-of-function data that show *GDF6* can promote tumor progression. Conversely, loss-of-function data indicate that *GDF6* is required for melanoma cell survival and, its loss abrogates tumor progression. Genetic epistasis and other data show that *GDF6* acts via the BMP signaling pathway to promote melanoma progression and melanoma cell survival. Our current hypothesis is that *GDF6* normally prevents terminal differentiation of melanocytes, thereby keeping cells in a progenitor-like state. Less differentiated progenitor-like cells are more apt to proliferate and support tumor progression.

These findings are important because *GDF6* represents a prime target for anti-melanoma therapy. *GDF6* encodes a secreted protein that is required for melanoma cell survival. Inhibition of *GDF6* has the potential to cause melanoma cell death and reduce tumor mass. Targeting *GDF6* protein could potentially be accomplished by inhibitors, such as monoclonal antibodies, that do not need to cross cell membranes. We are currently beginning to test this possibility by generating anti-*GDF6* antibodies.

Mechanistic insights into oncogenic glutamate receptor signaling in melanocytes and melanoma

Ana Neto and Craig Ceol

Program in Molecular Medicine and Department of Cancer Biology, University of Massachusetts Medical School, Worcester, Massachusetts, USA

Glutamate signaling, which is important in the central nervous system and in glial cell function, has recently been shown to have a role in melanoma progression. Human melanoma exome sequencing studies have identified activating mutations in metabotropic glutamate receptor 3 (GRM3). We hypothesize that altered glutamate signaling affects the development and function of melanocytes, endowing these cells with properties important for melanoma progression. Accordingly, understanding the role of glutamate signaling in melanocytes may inform how dysregulation of glutamate signaling is involved in melanoma progression. To test our hypothesis we use the miniCoopR assay, in which transgene-bearing melanocytes are derived in a *mitfa(lf)* background. Using this assay, we have determined how oncogenic GRM3 variants affect developing melanocytes and impact tumor formation. In embryonic melanocytes oncogenic GRM3 mutants disrupt trafficking of melanosomes, the pigment-producing organelles, whereas wild-type GRM3 does not. These and other data indicate that oncogenic GRM3 variants dysregulate cyclic AMP (cAMP) signaling, a heretofore unknown role for these oncogenes. Extending our analyses to tumors, we have found that expression of oncogenic GRM3 affects melanoma onset. These and additional data suggest that altered cAMP signaling can impact melanoma progression. Recent data have implicated defective cAMP signaling in the melanoma susceptibility of red-haired, fair-skinned individuals. Our data support the notion that disrupted cAMP signaling is a more pervasive contributor to melanoma, including in individuals that have incurred GRM3 mutations.

Dual mechanisms combine to mediate regeneration of zebrafish melanocytes following injury

Sharanya Iyengar, Craig Ceol

Program in Molecular Medicine and Department of Cancer Biology, University of Massachusetts Medical School, Worcester, MA, USA

Melanocytes, which can be lost during hair graying, injury and disease-related depigmentation, are replenished in mammals by resident stem cells. To gain insight into melanocyte regeneration we set out to identify whether melanocyte stem cells are present in adult zebrafish and how such cells might reconstitute the pigment pattern following injury. Using a targeted cell ablation approach we determined that *mitfa* is expressed not only in differentiated melanocytes but also in the cells that mediate melanocyte regeneration. When *mitfa*-positive cells are selectively ablated no melanocyte regeneration occurs. However, when ablation is performed in a *p53*-deficient background, melanocyte regeneration occurs, suggesting that death of the cells that mediate regeneration is dependent on *p53*. We then used *mitfa*-positivity to perform lineage-tracing experiments and assay whether unpigmented *mitfa*-expressing cells have stem cell properties. During regeneration, *mitfa*-positive cells can divide asymmetrically with one daughter cell differentiating and the other daughter remaining uncommitted; these are melanocyte stem cell divisions. In addition, some *mitfa*-positive cells directly differentiate during regeneration. Taken together, these data indicate that multiple mechanisms are used to re-establish pigmentation following injury and enable regeneration following subsequent rounds of ablation. We have used reporter assays and drug studies to assess whether pathways important for melanocyte development are also involved in regeneration. We found that Wnt signaling gets turned on during melanocyte regeneration and that Wnt inhibition after ablation of differentiated melanocytes delays regeneration. These studies have established a system by which regeneration can be traced with single-cell resolution and perturbations to regeneration analyzed in exquisite detail.

The novel oncogene *GDF6* promotes melanoma cell survival

The prevalence of *BRAFV600E* in nevi indicates that this mutation is not sufficient to cause melanoma. To identify new melanoma genes that could cooperate with *BRAFV600E*, we searched for abnormalities shared in both human melanomas and in a zebrafish *BRAFV600E*-driven melanoma model. We hypothesized that these conserved abnormalities would be enriched for genes that affect melanoma progression. In these analyses, we identified the *GDF6* gene, which encodes a member of the bone morphogenetic protein (BMP) family. *GDF6* genes in humans and zebrafish were recurrently copy number amplified in melanoma, and expression of the *GDF6* gene was observed in human and zebrafish melanomas but absent from normal melanocytes in both species. In functional analyses, overexpression of *GDF6* accelerated melanoma progression, whereas knockdown of *GDF6* in cultured A375 cells compromised melanoma formation in xenotransplantation assays. Knockdown of *GDF6* caused programmed cell death, which was rescued by an activated variant of the SMAD1 transcription factor, indicating that *GDF6* acts through the canonical BMP signaling pathway. Strikingly in tissue sections, GDF6 protein was readily detectable in more than 90% of melanomas, but was absent from melanocytes in normal adjacent skin. BMP pathway activity was likewise apparent in melanomas in a pattern that overlapped with GDF6 staining. Taken together, these data indicate that *GDF6* is a new melanoma oncogene that promotes melanoma cell survival and can be therapeutically targeted to induce melanoma cell death.

Identifying GDF6 as a novel pro-survival melanoma oncogene

To identify genes involved in tumor progression we defined regions of recurrent copy number variation in zebrafish melanomas and compared these regions to ones recurrently altered in human melanomas. In the set of genes that were recurrently amplified in both species we found the BMP factor GDF6. In analyses of both zebrafish and humans, GDF6 mRNA and protein were upregulated in melanomas as compared to normal melanocytes. In functional assessments, we found that overexpression of GDF6 accelerated melanoma onset in zebrafish and mouse xenotransplantation assays. Furthermore, knockdown of GDF6 in melanoma cell lines led to apoptotic cell death in culture *in vitro* and in *GDF6*-deficient tumors *in vivo*. Addition of recombinant GDF6 protein to the media prevented melanoma cells from undergoing GDF6 shRNA-induced apoptosis, suggesting that GDF6 acts as a secretory factor in aiding melanoma cell survival. GDF6, like other BMP factors, is predicted to signal through SMAD1/5/8 transcription factors, and similar defects were observed when SMAD1 was knocked down. To further define the relationship between GDF6 and SMAD1 in melanoma, GDF6 knockdown was performed in cells expressing a constitutively active SMAD1 variant. This variant rescued the death caused by GDF6 knockdown, suggesting that, at least in part, GDF6 acts through SMAD1 to promote melanoma cell survival. These data establish a role for BMP signaling in melanoma and identify a novel secretory factor, GDF6 that mediates this role. Discovery of this novel secretory factor that is present in a majority of human melanomas provides an excellent therapeutic target.

Figure 1. *GDF6* expression accelerates melanoma onset. A) Expression of *gdf6b* accelerates melanoma onset. In this assay melanocytes expressing the zebrafish *GDF6* ortholog *gdf6b* or *EGFP* were reconstituted in a *BRAF*^{V600E}-positive and *p53*-negative background. B) *GDF6* expression in control and *GDF6* overexpression cell lines. C) Cells that overexpress *GDF6* have accelerated melanoma onset in xenotransplantation.
